This hack is a strange mixture of awesome and ghoulish. [Andrew Sink] created a [3D printed version of his brain](#). He received a CD from an MRI session that contained the data obtained by the scan. Not knowing what to do with it he created a model of his brain.

Out of a number of images, some missing various parts of his head, he selected the one that was most complete. This image he brought into OisriX, a Mac program for handling DICOM files. He worked on the image for an hour dissecting away his own eyes, skull, and skin. An STL file containing his brain was brought over to NetFabb to see how it looked. There was still more dissection needed so [Andrew] turned to Blender. More bits and pieces of his skull's anatomy were dissected to pare it down to just the brain. But there were some lesions at the base of the brain that needed to be filled. With the help of [[Cindy Raggio](#)] these were filled in to complete the 3D image.

The usual steps sent it to the 3D printer to be produced at 0.2 mm resolution. It only took 49 hours to print at full-size. This brain was printed for fun, but we've seen [other 3D printed brain hacks which were used to save lives](#). How many people do you know that have a spare brain sitting around?
